

UNCERTAINTY AND THE MEDICAL INTERVIEW

TOWARDS SELF-ASSESSMENT IN MACHINE LEARNING MODELS

Jakob Drachmann Havtorn

- Welcome to my PhD defense.
- Thank you to the moderator and the assessment committee for taking part today.
- I will present my work on uncertainty estimation in AI systems for medical domains.
- I will start with an overview of the thesis followed by a brief introduction.
- Then I will present a selection of the research chapters.
- Finally, I will discuss the broader implications of the work.

OVERVIEW Thesis

- CHAPTER 1-3 INTRODUCTION, RESEARCH QUESTIONS, AND BACKGROUND
-
- CHAPTER 4 HIERARCHICAL VAES KNOW WHAT THEY DON'T KNOW
- CHAPTER 5 MODEL-AGNOSTIC OUT-OF-DISTRIBUTION DETECTION
USING COMBINED STATISTICAL TESTS
- CHAPTER 6 A BRIEF OVERVIEW OF UNSUPERVISED SPEECH
REPRESENTATION LEARNING
- CHAPTER 7 BENCHMARKING LATENT VARIABLE MODELS FOR SPEECH
- CHAPTER 8 AUTOMATED MEDICAL CODING ON MIMIC-III AND
MIMIC-IV: A CRITICAL REVIEW AND REPLICABILITY STUDY
- CHAPTER 9 A RETROSPECTIVE STUDY ON MACHINE LEARNING-
ASSISTED STROKE RECOGNITION FOR MEDICAL HELPLINE CALLS
-
- CHAPTER 10 DISCUSSION AND CONCLUSION

2024-03-04

UNCERTAINTY AND THE MEDICAL INTERVIEW

overview
└ Thesis

1. The thesis is structured into 10 chapters.
2. The first three chapters are introductory.
3. The next six chapters are research chapters.
4. The final chapter is a discussion and conclusion.

CHAPTER 1-3 INTRODUCTION, RESEARCH QUESTIONS, AND BACKGROUND

CHAPTER 10 DISCUSSION AND CONCLUSION

PROJECT Background

Industrial PhD project with Corti AI and DTU Compute.

- **2020-2023**
- **Collaboration** between academia and industry partially funded by InnovationFund Denmark.
- **Corti:** Using machine learning to augment communication in the healthcare sector.
- **Project goal:** Pursue research in machine learning at the interface between academic and company interests.

2024-03-04

PROJECT
Background

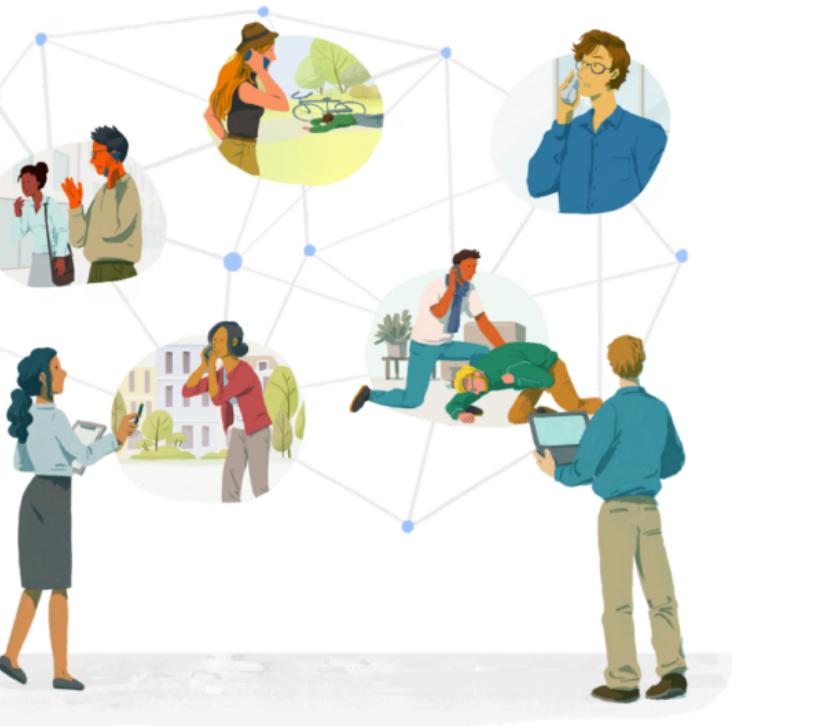

Industrial PhD project with Corti AI and DTU Compute.

- 2020-2023
- Collaboration between academia and industry partially funded by InnovationFund Denmark.
- Corti: Using machine learning to augment communication in the healthcare sector.
- Project goal: Pursue research in machine learning at the interface between academic and company interests.

INTRODUCTION Medical dialogue

Central to an **interaction** within a healthcare system is the **medical dialogue**:

- General practitioner
- Nurse
- Midwife
- Emergency medical dispatcher
- Paramedic
- Emergency room
- Health insurance

2024-03-04

UNCERTAINTY AND THE MEDICAL INTERVIEW

└ introduction
└ Medical dialogue

1. We focus on medical communication.
2. Involves many different parties.
3. Different contexts and purposes.
4. Busy emergency room, calls to emergency medical dispatchers, visits at general practitioners, etc.

INTRODUCTION
Medical dialogue

Central to an **interaction** within a healthcare system is the **medical dialogue**:

- General practitioner
- Nurse
- Midwife
- Emergency medical dispatcher
- Paramedic
- Emergency room
- Health insurance

Errors in medical dialogue

- Communication is everywhere in healthcare.
- It is complex, involving multiple participants, different contexts, and different purposes.

- Communication is everywhere in healthcare.
- It is complex, involving multiple participants, different contexts, and different purposes.

Errors in medical dialogue

- Communication is everywhere in healthcare.
- It is complex, involving multiple participants, different contexts, and different purposes.
- **Adverse events:** Failure of communication contributes to two out of three adverse events [54].
- **Preventability:** Many adverse outcomes are preventable [10].

UNCERTAINTY AND THE MEDICAL INTERVIEW

└ introduction

└ Errors in medical dialogue

1. So yes communication can be complex and noisy, but what are the consequences?
2. Failure of communication is a leading cause of adverse events.
3. Adverse events are episodes of medical error that result in harm to the patient.
4. Luckily, many of these are preventable, although exact numbers vary.
5. Better communication could help reduce these numbers.

Documenting medical encounters

- Almost every patient interaction has to be documented.
- Patient records, insurance claims, billing, research, training, legal purposes.

1. Another central aspect of medical communication is documentation.
2. Essential for a number of purposes
3. But, it is time-consuming and of varying quality.
4. (Ambulatory ≡ outpatient care, Tertiary ≡ specialized care)

- Almost every patient interaction has to be documented.
- Patient records, insurance claims, billing, research, training, legal purposes.

Documenting medical encounters

- Almost every patient interaction has to be documented.
- Patient records, insurance claims, billing, research, training, legal purposes.
- Time-consuming: Physicians spend 34-37% of their time on writing documentation [29, 52, 55]^a.
- Varying quality: Discharge summaries almost never meet *all* timeline, transmission, and content criteria. [24]^b

^aAmbulatory care across four specialties in four states and tertiary care at an academic medical center.

^bOutpatient visits, Yale-New Haven Hospital.

1. Another central aspect of medical communication is documentation.
2. Essential for a number of purposes
3. But, it is time-consuming and of varying quality.
4. (Ambulatory ≡ outpatient care, Tertiary ≡ specialized care)

How might machine learning help?

- Assist with documentation.
- Augment communication.
- Improve decision-making.

└ introduction

└ How might machine learning help?

2024-03-04

- Assist with documentation.
- Augment communication.
- Improve decision-making.

How might machine learning help?

- **Assist** with documentation.
- **Augment** communication.
- **Improve** decision-making.
- **Reduce** the impact of medical errors and adverse events.
- **Free up** time spent on documentation for patient care.

UNCERTAINTY AND THE MEDICAL INTERVIEW

└ introduction

└ How might machine learning help?

1. Machine learning can help in many ways.
2. The main goal of augmenting communication is:
 - Reduce the impact.
 - Free up time.

Building a decision-support system

2024-03-04

UNCERTAINTY AND THE MEDICAL INTERVIEW

INTRODUCTION
Building a decision-support system

└ introduction

└ Building a decision-support system

1. We will take a modular approach to building a decision-support system.
2. First we need source data
3. Then we need to convert it into representations useful for downstream tasks.
4. Then we can perform the downstream tasks.
5. Finally, we need to estimate the reliability of our data, representations, and predictions.

Building a decision-support system

- **Source data:** Speech or text (potentially images, video, electronic health records, etc.).

TEXT

A blue horizontal bar with vertical white lines at both ends, containing the word 'TEXT' in the center.

SPEECH

A green horizontal bar with vertical white lines at both ends, containing the word 'SPEECH' in the center.

Defining OOD detection

2024-03-04

Enable models to distinguish the training data distribution $p(x)$ from any other distribution $\tilde{p}(x)$.
Do this for any given single observation, i.e. answer the question:

"Was x sampled from $p(x)$ or not?"

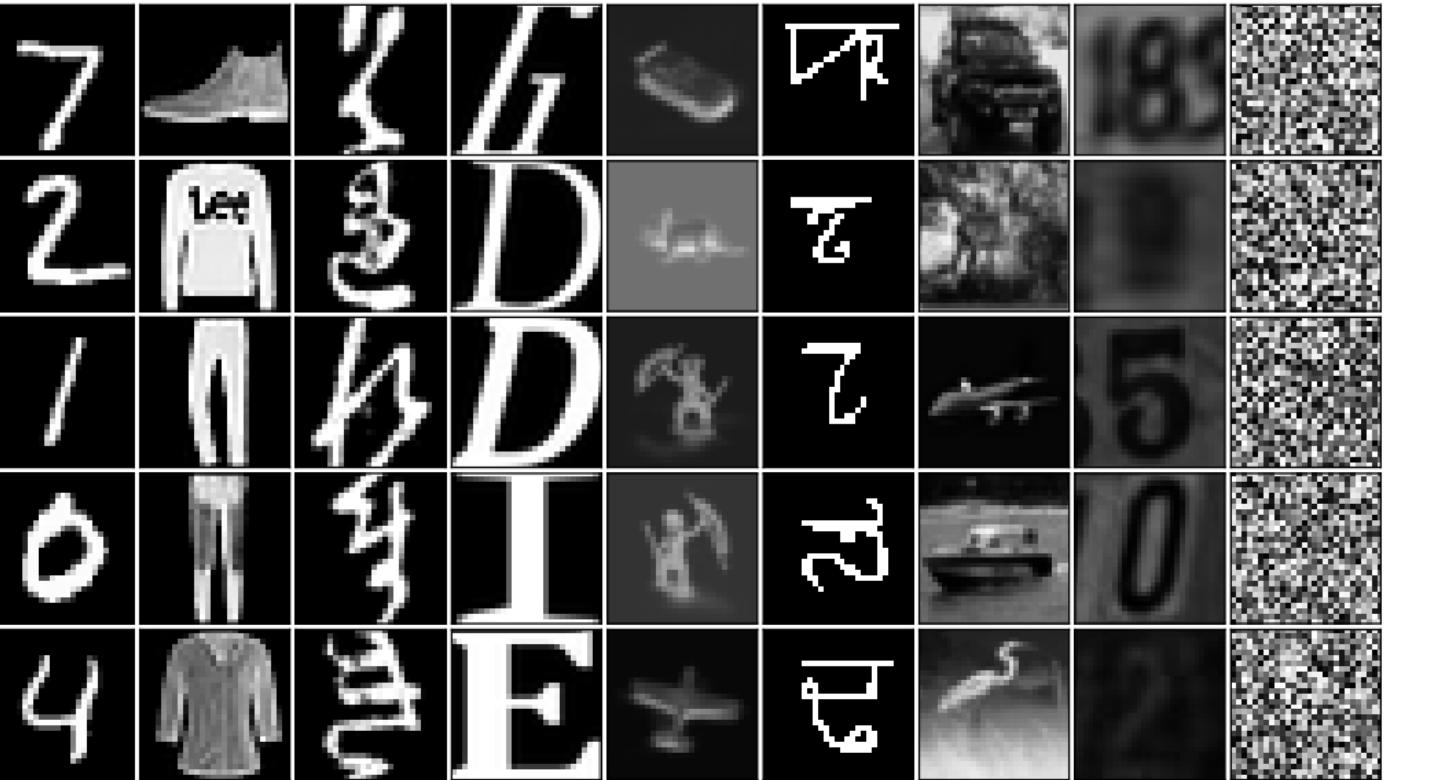

In distribution?**UNCERTAINTY AND THE MEDICAL INTERVIEW**

└ hierarchical vaes know what they don't know

└ In distribution?

1. Datasets can overlap quite a bit in their raw data space.
2. What we usually care about is a more semantic notion of similarity.

Out of distribution?**UNCERTAINTY AND THE MEDICAL INTERVIEW**

└ hierarchical vaes know what they don't know

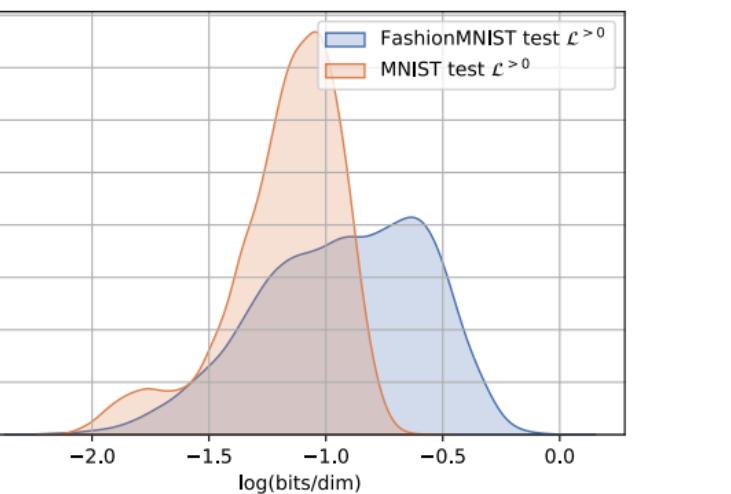

└ Out of distribution?

1. Datasets can overlap quite a bit in their raw data space.
2. What we usually care about is a more semantic notion of similarity.

Out-of-distribution detection with generative models

- Generative models learn to approximate the **data distribution** $p(x)$.
- The likelihood of the model given a sample x is a measure of how well the model **explains the data**.
- **Model likelihood** has long been thought of as useful for OOD detection [5].

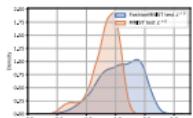

UNCERTAINTY AND THE MEDICAL INTERVIEW

↳ hierarchical vae's know what they don't know

↳ Out-of-distribution detection with generative models

2024-03-04

- Generative models learn to approximate the data distribution $p(x)$.
- The likelihood of the model given a sample x is a measure of how well the model explains the data.
- Model likelihood has long been thought of as useful for OOD detection [5].

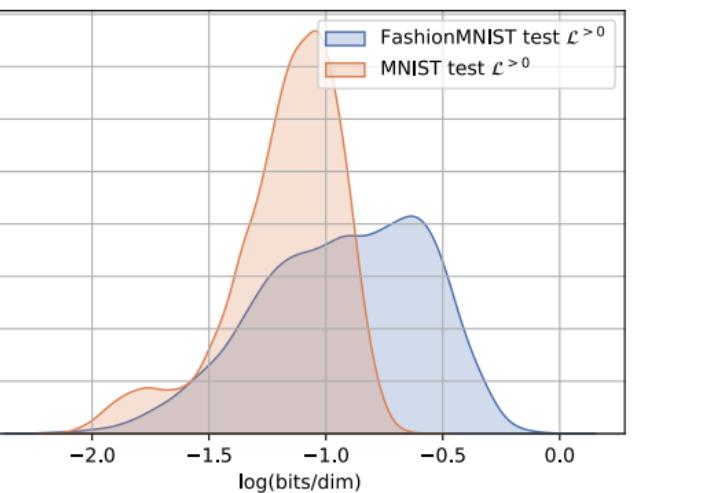

Out-of-distribution detection with generative models

- Generative models learn to approximate the **data distribution** $p(x)$.
- The likelihood of the model given a sample x is a measure of how well the model **explains the data**.
- **Model likelihood** has long been thought of as useful for OOD detection [5].

HVAE trained on FashionMNIST evaluated on FashionMNIST and MNIST.

Out-of-distribution detection with generative models

2024-03-04

HIERARCHICAL VAES KNOW WHAT THEY DON'T KNOW

Hierarchical VAE

We choose the hierarchical VAE as our model [33, 48].

$$p_{\theta}(x) = \int p_{\theta}(x, z) dz = \int p_{\theta}(x|z)p_{\theta}(z) dz$$

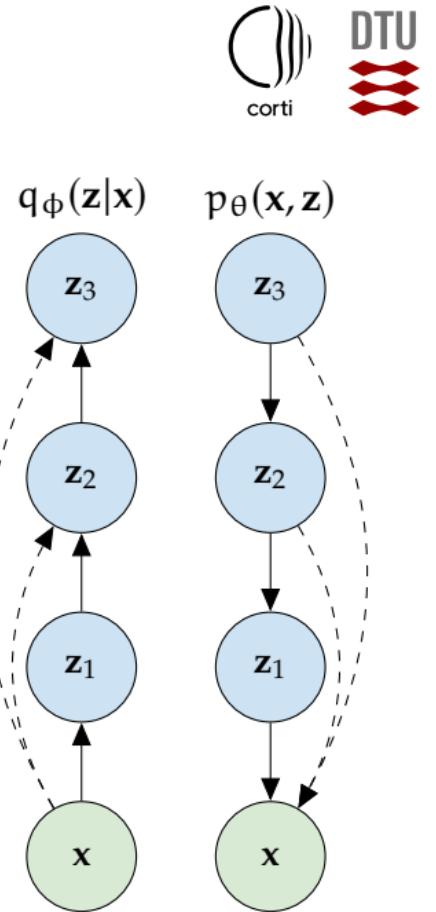

Specifically we use

- ① a three-layered hierarchical VAE with bottom-up inference and deterministic skip-connections for both inference and generation.

Generative model: $p_{\theta}(x|z) = p_{\theta}(x|z_1)p_{\theta}(z_1|z_2)p(z_2)$,

Inference model: $q_{\phi}(z|x) = q_{\phi}(z_1|x)q_{\phi}(z_2|z_1)q_{\phi}(z_3|z_2)$.

- ② a ten-layered layered Bidirectional-Inference Variational Autoencoder (BIVA) [40].

2024-03-04

UNCERTAINTY AND THE MEDICAL INTERVIEW

q_φ(z|x) p_θ(x, z)

z₃ z₃
z₂ z₂
z₁ z₁
x x

1. We want to explain why HVAEs fail at OOD detection when using their likelihood.
2. And how to fix them.

What is wrong with the ELBO for OOD detection?

We can split the ELBO into two terms

$$\mathcal{L}(\mathbf{x}; \theta, \phi) = \mathbb{E}_{q_\phi(\mathbf{z}|\mathbf{x})} \left[\log \frac{p_\theta(\mathbf{x}, \mathbf{z})}{q_\phi(\mathbf{z}|\mathbf{x})} \right] = \underbrace{\mathbb{E}_{q_\phi(\mathbf{z}|\mathbf{x})} [\log p_\theta(\mathbf{x}|\mathbf{z})]}_{\text{reconstruction likelihood}} - \underbrace{D_{\text{KL}}(q_\phi(\mathbf{z}|\mathbf{x}) \parallel p(\mathbf{z}))}_{\text{regularization penalty}}. \quad (1)$$

The first term is high if the data is well-explained by \mathbf{z} . The second term we can rewrite as,

$$D_{\text{KL}}(q_\phi(\mathbf{z}|\mathbf{x}) \parallel p(\mathbf{z})) = \mathbb{E}_{q_\phi(\mathbf{z}|\mathbf{x})} \left[\sum_{i=1}^{L-1} \log \frac{p_\theta(\mathbf{z}_i|\mathbf{z}_{i+1})}{q_\phi(\mathbf{z}_i|\mathbf{z}_{i-1})} + \log \frac{p_\theta(\mathbf{z}_L)}{q_\phi(\mathbf{z}_L|\mathbf{z}_{L-1})} \right]. \quad (2)$$

Since the individual terms are computed by summing over the dimensionality of \mathbf{z}_i , the absolute log-ratios grow with $\text{dim}(\mathbf{z}_i)$.

Since the lower-most latent variables are usually higher dimensional than top ones, these are weighted higher in the ELBO.

2024-03-04

UNCERTAINTY AND THE MEDICAL INTERVIEW

↳ hierarchical vae's know what they don't know

↳ What is wrong with the ELBO for OOD detection?

We can split the ELBO into two terms

$$\mathcal{L}(\mathbf{x}; \theta, \phi) = \mathbb{E}_{q_\phi(\mathbf{z}|\mathbf{x})} \left[\log \frac{p_\theta(\mathbf{x}, \mathbf{z})}{q_\phi(\mathbf{z}|\mathbf{x})} \right] = \mathbb{E}_{q_\phi(\mathbf{z}|\mathbf{x})} [\log p_\theta(\mathbf{x}|\mathbf{z})] - D_{\text{KL}}(q_\phi(\mathbf{z}|\mathbf{x}) \parallel p(\mathbf{z})). \quad (1)$$

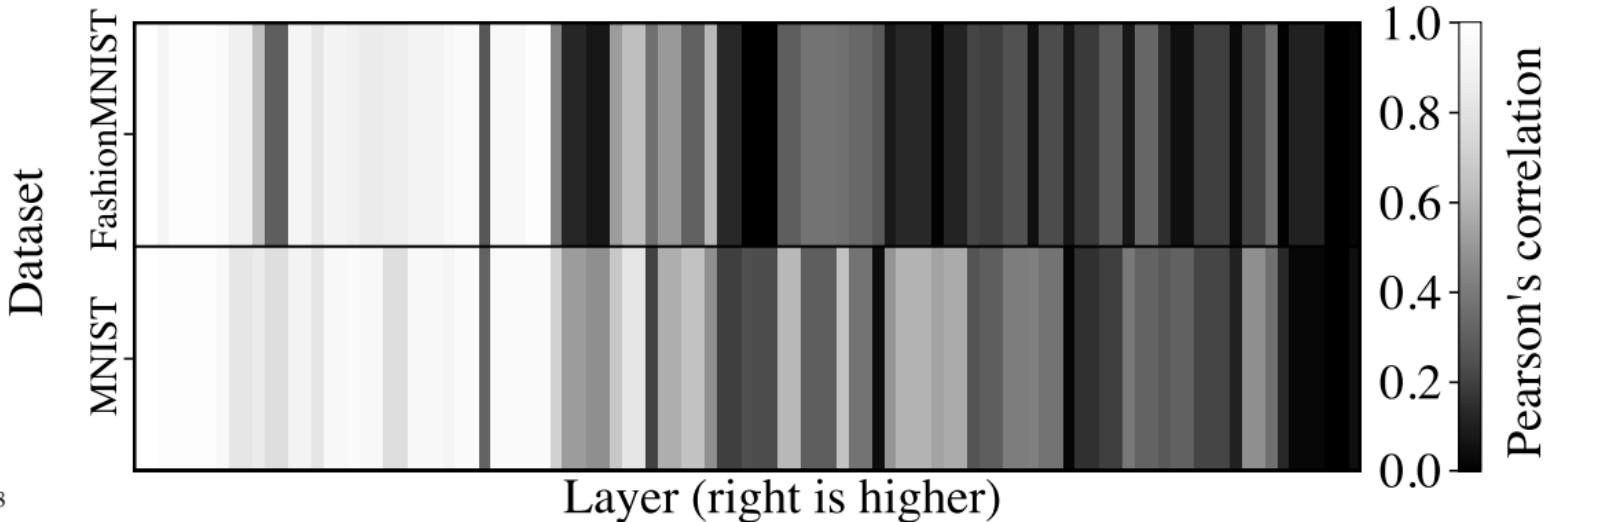

$$D_{\text{KL}}(q_\phi(\mathbf{z}|\mathbf{x}) \parallel p(\mathbf{z})) = \mathbb{E}_{q_\phi(\mathbf{z}|\mathbf{x})} \left[\sum_{i=1}^{L-1} \log \frac{p_\theta(\mathbf{z}_i|\mathbf{z}_{i+1})}{q_\phi(\mathbf{z}_i|\mathbf{z}_{i-1})} + \log \frac{p_\theta(\mathbf{z}_L)}{q_\phi(\mathbf{z}_L|\mathbf{z}_{L-1})} \right]. \quad (2)$$

The first term is high if the data is well-explained by \mathbf{z} . The second term we can rewrite as,
 Since the individual terms are computed by summing over the dimensionality of \mathbf{z}_i , the absolute log-ratios grow with $\text{dim}(\mathbf{z}_i)$.
 Since the lower-most latent variables are usually higher dimensional than top ones, these are weighted higher in the ELBO.

What do the lowest latent variables represent?

Absolute Pearson correlations between data representations in all layers of the inference network of a hierarchical VAE trained on FashionMNIST and of another trained on MNIST.

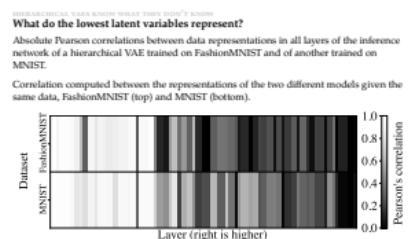

Correlation computed between the representations of the two different models given the same data, FashionMNIST (top) and MNIST (bottom).

UNCERTAINTY AND THE MEDICAL INTERVIEW

↳ hierarchical vae's know what they don't know

↳ What do the lowest latent variables represent?

Likelihood ratios

We suggest to define a likelihood ratio score [9] using the ELBO $\mathcal{L}(x)$ and a relaxed bound $\mathcal{L}^{>k}(x)$.

$$\text{LLR}^{>k}(x) \equiv \mathcal{L}(x) - \mathcal{L}^{>k}(x), \quad (3)$$

where the exact form of the bounds is,

$$\mathcal{L} = \log p_\theta(x) - D_{\text{KL}}(q_\phi(z|x) \| p_\theta(z|x)), \quad (4)$$

$$\mathcal{L}^{>k} = \log p_\theta(x) - D_{\text{KL}}(p_\theta(z_{<k}|z_{>k})q_\phi(z_{>k}|x) \| p_\theta(z|x)).$$

In the likelihood ratio $\log p_\theta(x)$ cancels out and only the KL-divergences from the approximate to the true posterior remain.

$$\begin{aligned} \text{LLR}^{>k}(x) &= -D_{\text{KL}}(q_\phi(z|x) \| p_\theta(z|x)) \\ &\quad + D_{\text{KL}}(p_\theta(z_{<k}|z_{>k})q_\phi(z_{>k}|x) \| p_\theta(z|x)). \end{aligned} \quad (5)$$

UNCERTAINTY AND THE MEDICAL INTERVIEW

hierarchical vaes know what they don't know

Likelihood ratios

2024-03-04

HIERARCHICAL VAES KNOW WHAT THEY DON'T KNOW
Likelihood ratios
We suggest to define a likelihood ratio score [9] using the ELBO $\mathcal{L}(x)$ and a relaxed bound $\mathcal{L}^{>k}(x)$.
 $\text{LLR}^{>k}(x) \equiv \mathcal{L}(x) - \mathcal{L}^{>k}(x),$
where the exact form of the bounds is,

$$\mathcal{L} = \log p_\theta(x) - D_{\text{KL}}(q_\phi(z|x) \| p_\theta(z|x)),$$

$$\mathcal{L}^{>k} = \log p_\theta(x) - D_{\text{KL}}(p_\theta(z_{<k}|z_{>k})q_\phi(z_{>k}|x) \| p_\theta(z|x)).$$

In the likelihood ratio $\log p_\theta(x)$ cancels out and only the KL-divergences from the approximate to the true posterior remain.

$$\text{LLR}^{>k}(x) = -D_{\text{KL}}(q_\phi(z|x) \| p_\theta(z|x))$$

$$+ D_{\text{KL}}(p_\theta(z_{<k}|z_{>k})q_\phi(z_{>k}|x) \| p_\theta(z|x)).$$

1. Write likelihood-ratio using the exact form of the bounds including intractable KL-divergence.

The importance weighted autoencoder (IWAE) bound is tight with the true likelihood in the limit of infinite samples, $S \rightarrow \infty$ [8],

$$\mathcal{L}_S = \mathbb{E}_{q(\mathbf{z}|\mathbf{x})} \left[\log \frac{1}{N} \sum_{s=1}^S \frac{p(\mathbf{x}, \mathbf{z}^{(s)})}{q(\mathbf{z}^{(s)}|\mathbf{x})} \right] \leq \log p_\theta(\mathbf{x}), \quad (6)$$

Consequently, by importance sampling the ELBO, $D_{KL}(q_\phi(\mathbf{z}|\mathbf{x}) \parallel p_\theta(\mathbf{z}|\mathbf{x})) \rightarrow 0$ and our likelihood ratio reduces to the KL-divergence of $\mathcal{L}^{>k}$.

$$LLR_S^{>k}(\mathbf{x}) \rightarrow D_{KL}(p(\mathbf{z}_{\leq k}|\mathbf{z}_{>k})q(\mathbf{z}_{>k}|\mathbf{x}) \parallel p(\mathbf{z}|\mathbf{x})). \quad (7)$$

$LLR_S^{>k}(\mathbf{x})$ performs KL-divergence-based OOD detection using top-most latent variables.

UNCERTAINTY AND THE MEDICAL INTERVIEW

- └ hierarchical vae know what they don't know
- └ Importance sampling the ELBO

2024-03-04

HIERARCHICAL VAEs KNOW WHAT THEY DON'T KNOW
Importance sampling the ELBO

The importance weighted autoencoder (IWAE) bound is tight with the true likelihood in the limit of infinite samples, $S \rightarrow \infty$ [8].

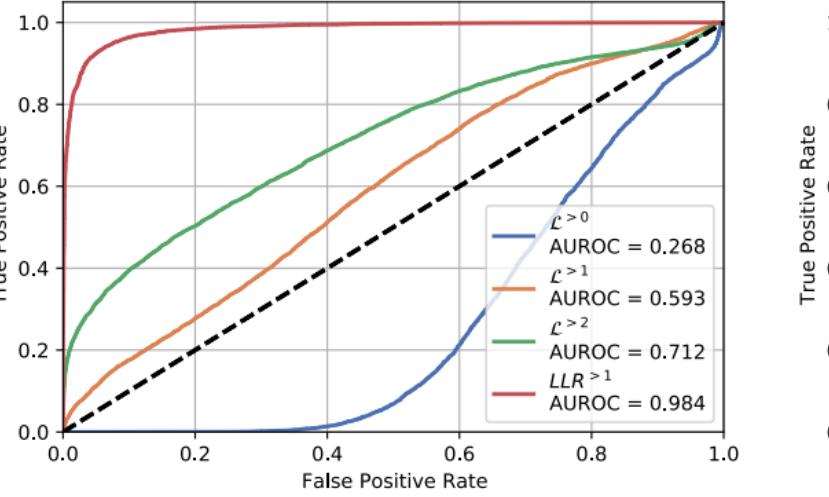

$$\mathcal{L}_S = \mathbb{E}_{q(\mathbf{z}|\mathbf{x})} \left[\log \frac{1}{N} \sum_{s=1}^S \frac{p(\mathbf{x}, \mathbf{z}^{(s)})}{q(\mathbf{z}^{(s)}|\mathbf{x})} \right] \leq \log p_\theta(\mathbf{x}), \quad (6)$$

Consequently, by importance sampling the ELBO, $D_{KL}(q_\phi(\mathbf{z}|\mathbf{x}) \parallel p_\theta(\mathbf{z}|\mathbf{x})) \rightarrow 0$ and our likelihood ratio reduces to the KL-divergence of $\mathcal{L}^{>k}$.

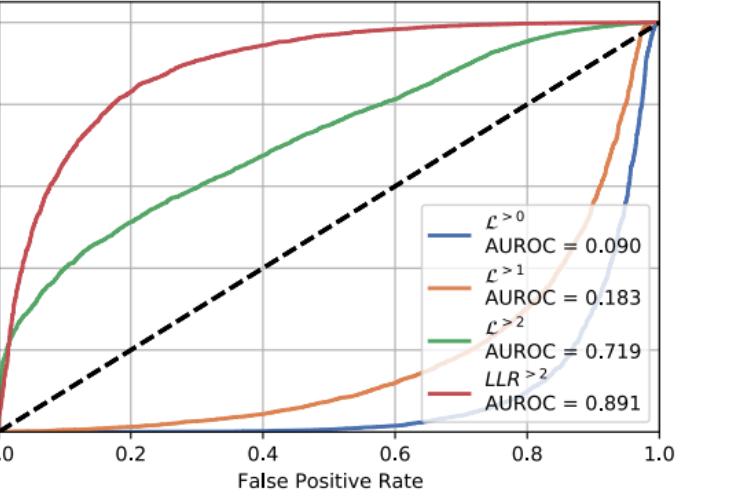

$$LLR_S^{>k}(\mathbf{x}) \rightarrow D_{KL}(p(\mathbf{z}_{\leq k}|\mathbf{z}_{>k})q(\mathbf{z}_{>k}|\mathbf{x}) \parallel p(\mathbf{z}|\mathbf{x})). \quad (7)$$

$LLR_S^{>k}(\mathbf{x})$ performs KL-divergence-based OOD detection using top-most latent variables.

- Key observations:
 - The likelihood of a generative model is not a good score for OOD detection [41].
 - Strong correlations between some latent variables for different datasets.
- Provide explanation for why the likelihood fails fro OODD for HVAEs.
- Proposed a likelihood-ratio score, $LLR^{>k}$, that uses the conditional prior for the bottom-most latent variables in the hierarchy and showed its effectiveness.

UNCERTAINTY AND THE MEDICAL INTERVIEW

a brief overview of unsupervised speech representation learning

Autoregressive Predictive Coding (APC)

A BRIEF OVERVIEW OF UNSUPERVISED SPEECH REPRESENTATION LEARNING
Autoregressive Predictive Coding (APC)

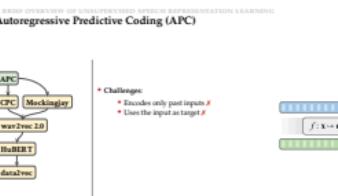

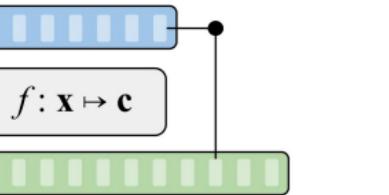

• Task: Predict future inputs.
• Input/target: Log-mel spectrogram.
• Architecture: RNN/Transformer decoder.
• Slow features: Predict k steps ahead.

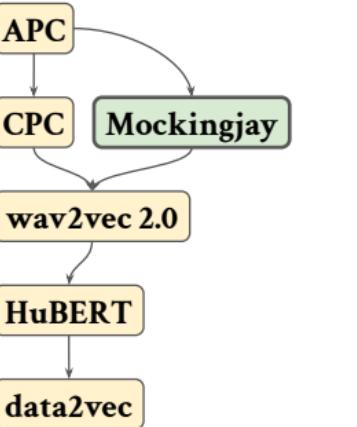

The diagram shows the APC architecture. It consists of several components: APC, CPC, Mockingjay, wav2vec 2.0, HuBERT, and data2vec. The APC and CPC components are highlighted in green, while the others are in orange. The Mockingjay component is shown with a curved arrow pointing to it from the APC component. The wav2vec 2.0 component is shown with a curved arrow pointing to it from the CPC component. The HuBERT and data2vec components are shown with curved arrows pointing to them from the wav2vec 2.0 component. The data2vec component is also shown with a curved arrow pointing to it from the HuBERT component. The diagram also includes a legend and a small diagram of a speech spectrogram.

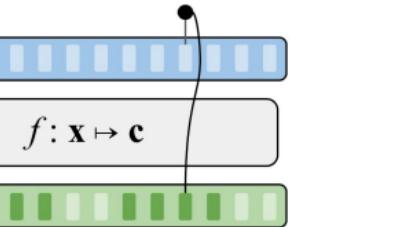

- Challenges:

- Encodes only past inputs ✗
- Uses the input as target ✗

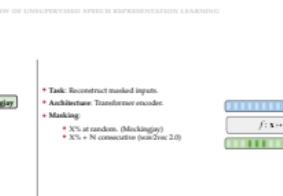

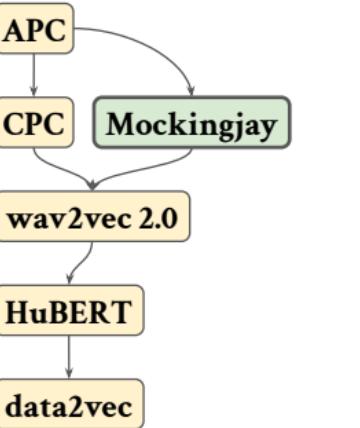

- **Task:** Reconstruct masked inputs.
- **Architecture:** Transformer encoder.
- **Masking:**
 - X% at random. (Mockingjay)
 - X% + N consecutive (wav2vec 2.0)

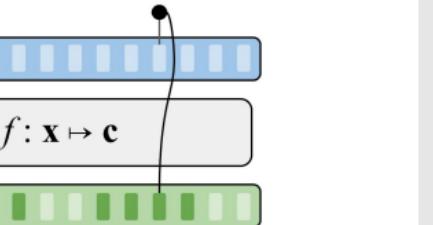

2024-03-04

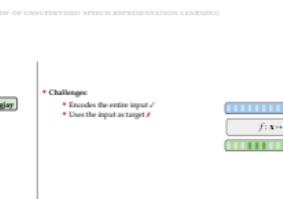

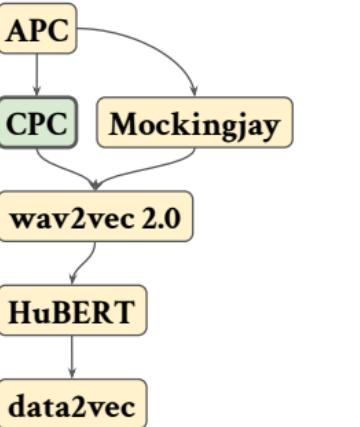

- Challenges:

- Encodes the entire input ✓
- Uses the input as target ✗

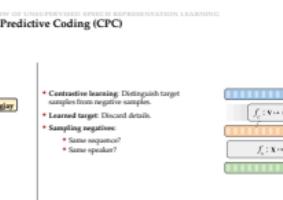

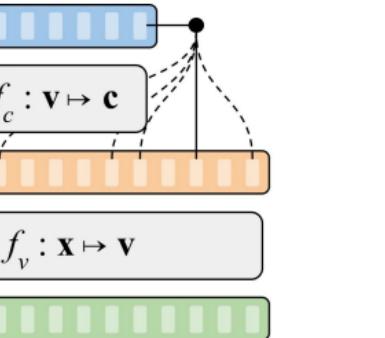

2024-03-04

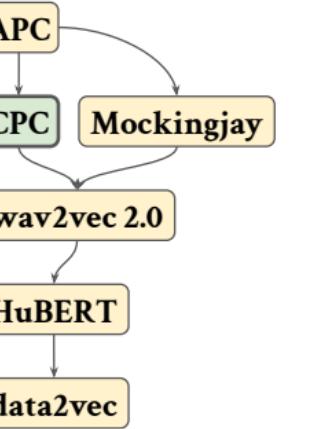

- **Contrastive learning:** Distinguish target samples from negative samples.
- **Learned target:** Discard details.
- **Sampling negatives:**
 - Same sequence?
 - Same speaker?

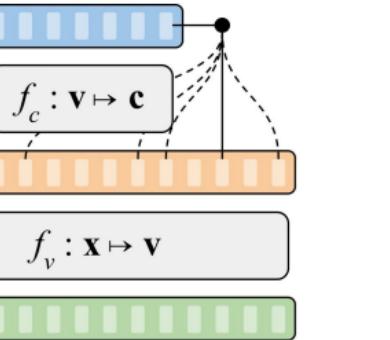

1. Contrastive models allow using a learned target. Discard unimportant details of input.
2. Negative sampling is a challenge and requires careful design.
3. Sampling different speakers as negatives learns strong speaker-identities.

2024-03-04

- **Main conclusions:**
 - The most popular self-supervised speech models can be compactly described by a few core design choices.
 - Many of these design choices are mirrored in earlier work on speech embedding models.
- **Open questions and limitations:**
 - Which design choices benefit which downstream tasks?
 - It is difficult to compare methods as model size and evaluation procedures differ widely between papers.

SPEECH

INTRODUCTION, RESEARCH QUESTIONS, AND BACKGROUND

A BRIEF OVERVIEW OF UNSUPERVISED SPEECH

REPRESENTATION LEARNING

A RETROSPECTIVE STUDY ON MACHINE LEARNING-
ASSISTED STROKE RECOGNITION FOR MEDICAL HELPLINE CALLS

DISCUSSION AND CONCLUSION

- Stroke is the second leading cause of death (11.6%) and third leading cause of death and disability combined (5.7%) worldwide [20, 30, 35].
- Effective treatment is very **time-sensitive** [4, 56].
- The gateway to **ambulance transport and hospital admittance** is through **prehospital telehealth services**.
- **Mobile stroke units** have made it possible to deliver advanced treatment faster [22, 42].
- The effectiveness of mobile stroke units hinges on **call-taker recognition of stroke** [22, 42].
- Approximately half of all patients with stroke do not receive the correct triage for their condition from call-takers [7, 45, 58].

UNCERTAINTY AND THE MEDICAL INTERVIEW

- 2024-03-04

 - └ Stroke

1. [45]: Systematic review, recall = 41-83%, precision = 42-68%.
2. [58]: 1-1-2 calls at CEMS, recall = 66.2%, precision = 30.2%.
3. [7]: Systematic review, recall = 66.2%, precision = 30.2%.
4. Recognition rates also vary widely by call-center.

A RETROSPECTIVE STUDY ON MACHINE LEARNING-ASSISTED STROKE RECOGNITION
FOR MEDICAL HELPLINE CALLS
Stroke

- Stroke is the second leading cause of death (11.6%) and third leading cause of death and disability combined (5.7%) worldwide [20, 30, 35].
- Effective treatment is very **time-sensitive** [4, 56].
- The gateway to **ambulance transport and hospital admittance** is through **prehospital telehealth services**.
- **Mobile stroke units** have made it possible to deliver advanced treatment faster [22, 42].
- The effectiveness of mobile stroke units hinges on **call-taker recognition of stroke** [22, 42].
- Approximately half of all patients with stroke do not receive the correct triage for their condition from call-takers [7, 45, 58].

The study

- Collaboration between **Corti** and the **Copenhagen Emergency Medical Services (CEMS)** ("Region Hovedstadens Akutberedskab").
- CEMS provides prehospital telehealth services in the Capital Region of Denmark (1.9M people).
- CEMS operates the 1-1-2 emergency line (similar to 9-1-1) and the 1813 medical helpline (non-life-threatening conditions when general practitioner is unavailable).
- We wanted to investigate if a machine learning model could assist call-takers of 1813 in recognizing stroke.

Male	153,050 (44.49%)	408 (53.90%)	152,642 (44.47%)
65+ years	65,652 (19.08%)	555 (73.32%)	65,097 (18.96%)
Age (mean ± std.)	44.31 ± 20.10	71.51 ± 13.41	44.25 ± 20.08

UNCERTAINTY AND THE MEDICAL INTERVIEW

a retrospective study on machine learning-assisted stroke recognition for medical helpline calls

Population characteristics of test set

1. Prevalence of stroke is less than a quarter percent, one in every 400 calls.
2. The mean age of stroke calls is 71.5 years, older than general callers.
3. Males are a bit more likely to call with a stroke compared to females.
4. Other datasets (training, validation) have similar characteristics.

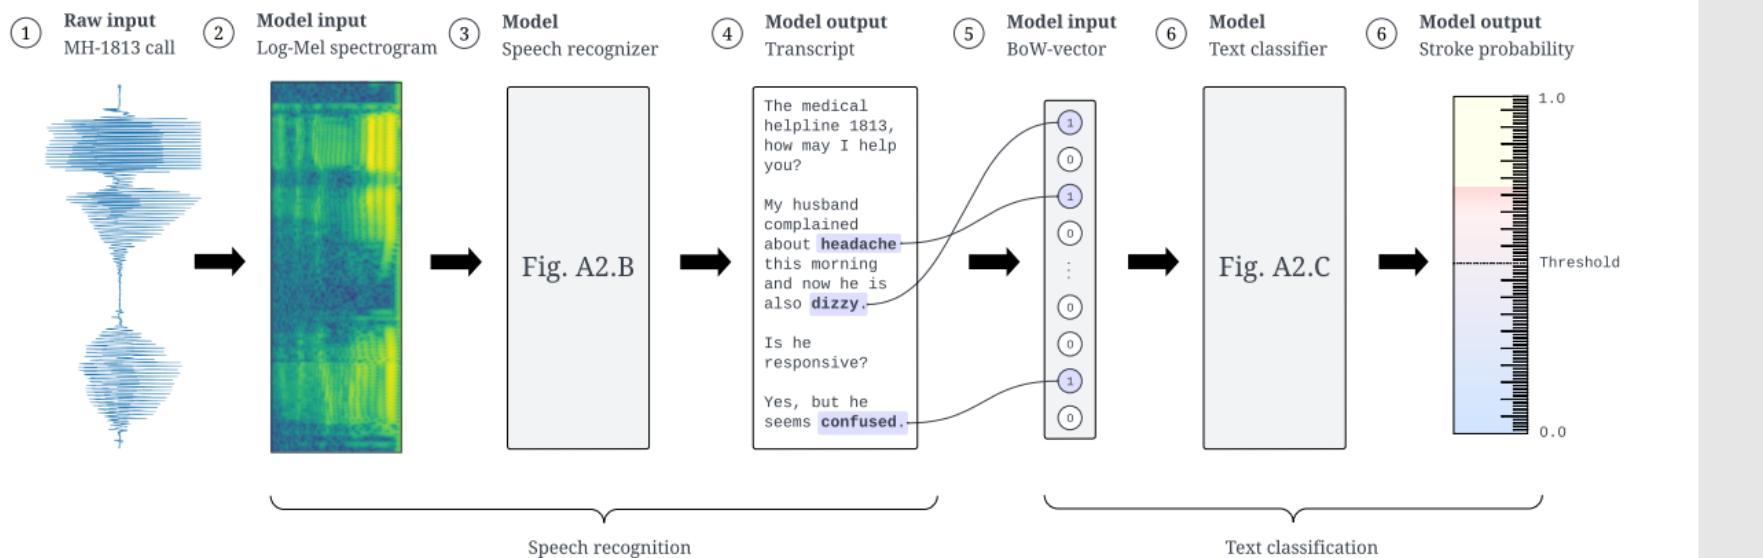

Subset	All calls	Stroke calls	Non-stroke
Num. calls	344,030	757	343,273
Female	190,974 (55.51%)	349 (46.10%)	190,625 (55.53%)
Male	153,050 (44.49%)	408 (53.90%)	152,642 (44.47%)
65+ years	65,652 (19.08%)	555 (73.32%)	65,097 (18.96%)
Age (mean ± std.)	44.31 ± 20.10	71.51 ± 13.41	44.25 ± 20.08

A RETROSPECTIVE STUDY ON MACHINE LEARNING-ASSISTED STROKE RECOGNITION FOR MEDICAL HELPLINE CALLS

Model design

A. Schematic Overview of Stroke Classification Pipeline

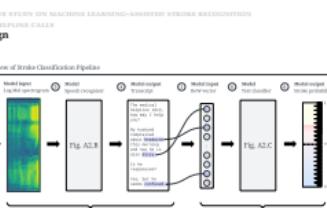

UNCERTAINTY AND THE MEDICAL INTERVIEW

a retrospective study on machine learning-assisted stroke recognition for medical helpline calls

Model design

2024-03-04

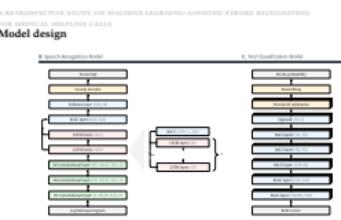

1. Same structure as the decision-support system sketched in the overview slides.

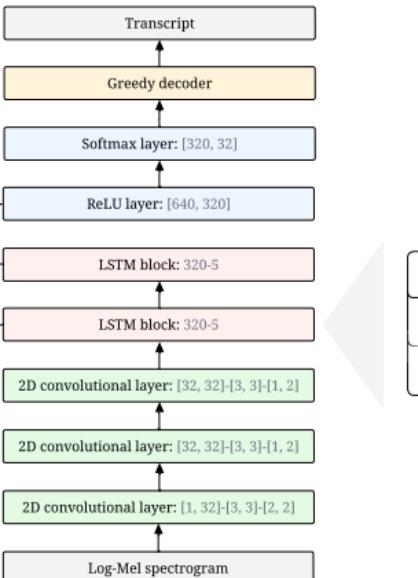

Model design

UNCERTAINTY AND THE MEDICAL INTERVIEW

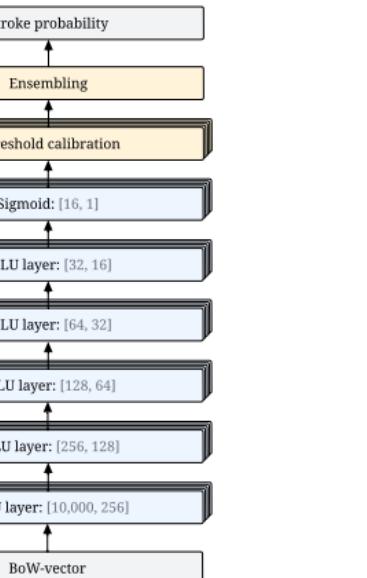

- └ a retrospective study on machine learning-assisted stroke recognition for medical helpline calls
 - └ Model design

B. Speech Recognition Model

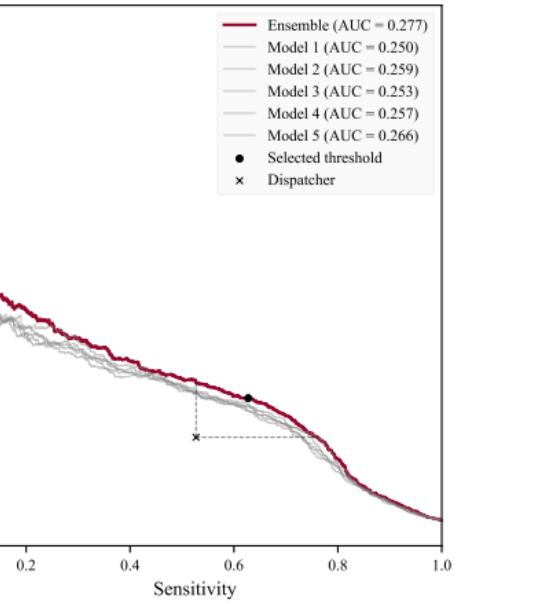

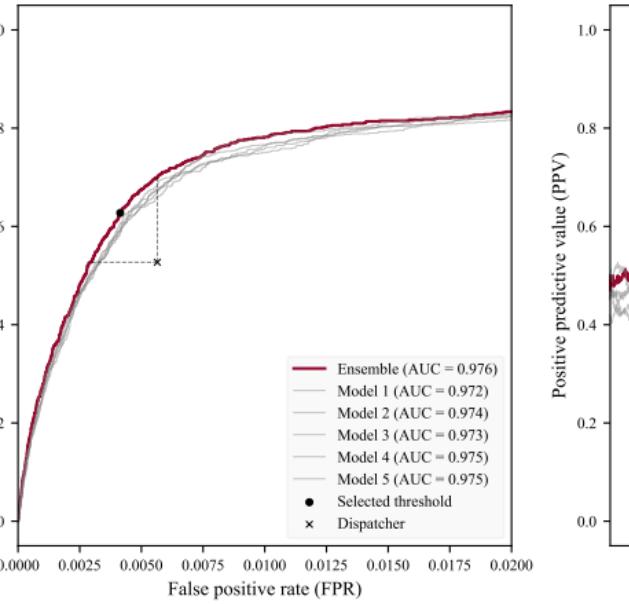

C. Text Classification Model

A RETROSPECTIVE STUDY ON MACHINE LEARNING-ASSISTED STROKE RECOGNITION FOR MEDICAL HELPLINE CALLS

Main results

ROC curve and PPV-sensitivity curve (precision-recall curve). Models 1-5 are the individual models that make up the ensemble model.

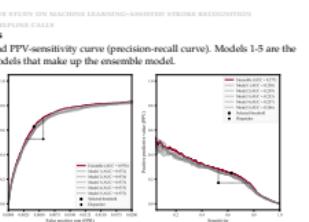

2024-03-04

UNCERTAINTY AND THE MEDICAL INTERVIEW

a retrospective study on machine learning-assisted stroke recognition for medical helpline calls

Main results

Main results

Confusion matrices of predictions for call takers and the model on the test set. Numbers for the model are given as the rounded mean over eleven runs.

		Ground truth labels	
		Positives	Negatives
Call taker predictions	Positives	True positives 399	False positives 1,938
	Negatives	False negatives 358	True negatives 341,335

		Ground truth labels	
		Positives	Negatives
Model predictions	Positives	True positives 477	False positives 1,440
	Negatives	False negatives 280	True negatives 341,833

UNCERTAINTY AND THE MEDICAL INTERVIEW

a retrospective study on machine learning-assisted stroke recognition
for medical helpline calls

2024-03-04
Main results

Confusion matrices of predictions for call takers and the model on the test set. Numbers for the model are given as the rounded mean over eleven runs.			
Call takers		Model	
		Positives	Negatives
True positives	399	True positives	477
False positives	1,938	False positives	1,440
True negatives	341,335	True negatives	341,833
False negatives	358	False negatives	280

1. In absolute numbers, the model correctly identifies 78 cases of stroke missed by call-takers.
2. The model also reduces the number of false positives by about 500 from 1938 to 1440.

A RETROSPECTIVE STUDY ON MACHINE LEARNING-ASSISTED STROKE RECOGNITION

Future work

- Machine learning
 - Learning to predict directly from audio data (SSL).
 - Learning to defer to predict methods [57].
- Clinical applications
 - Mental health: Screening for suicide risk in emergency and medical helpline calls.
 - Maternity ward: Screening for serious pregnancy complications.

UNCERTAINTY AND THE MEDICAL INTERVIEW

- 2024-03-04
- └ a retrospective study on machine learning-assisted stroke recognition for medical helpline calls
 - └ Future work

1. Learning to defer to predict is related to uncertainty estimation.

- Machine learning
 - Learning to predict directly from audio data (SSL).
 - Learning to defer to predict methods [57].
- Clinical applications
 - Mental health: Screening for suicide risk in emergency and medical helpline calls.
 - Maternity ward: Screening for serious pregnancy complications.

DISCUSSION AND CONCLUSION

PRESENTATION

The broad picture: The thesis topic since 2020

2020 Project start

- Out-of-distribution detection with generative models: Mysterious new topic.
- Speech representation/recognition: Inflection point between supervised methods and new self-supervised approaches.

└ discussion

└ The broad picture: The thesis topic since 2020

2024-03-04

The broad picture: The thesis topic since 2020

2020 Project start

- Out-of-distribution detection with generative models: Mysterious new topic.
- Speech representation/recognition: Inflection point between supervised methods and new self-supervised approaches.

2024 Project end

- Out-of-distribution detection is a mature field with a wide range of methods.
- Self-supervised learning is the dominant paradigm in speech recognition - challenged by weak labelling.

DISCUSSION

The broad picture: The thesis topic since 2020

2020 Project start

- Out-of-distribution detection with generative models: Mysterious new topic.
- Speech representation/recognition: Inflection point between supervised methods and new self-supervised approaches.

2024 Project end

- Out-of-distribution detection is a mature field with a wide range of methods.
- Self-supervised learning is the dominant paradigm in speech recognition - challenged by weak labelling.
- Clinical research is increasingly becoming interested in the use of machine learning.

UNCERTAINTY AND THE MEDICAL INTERVIEW

↳ discussion

↳ The broad picture: The thesis topic since 2020

2024-03-04

What lies ahead

- Selective out-of-distribution detection

Two pairs of distributions may have identical divergence, but in different dimensions. How do we control features in black-box models?

- Self-supervised learning in the wild

Does the recent progress on academic datasets translate to this real-world setting?

Speech recognition has been the cornerstone benchmarking task. How do we target spoken language understanding directly?

- Large language models in medical dialogue

LLMs will likely play a central role in the future of medical documentation and communication. How do we get a grip of their uncertainty?

↳ discussion

↳ What lies ahead

2024-03-04

- Selective out-of-distribution detection

Two pairs of distributions may have identical divergence, but in different dimensions. How do we control features in black-box models?

- Self-supervised learning in the wild

Does the recent progress on academic datasets translate to this real-world setting? Speech recognition has been the cornerstone benchmarking task. How do we target spoken language understanding directly?

- Large language models in medical dialogue

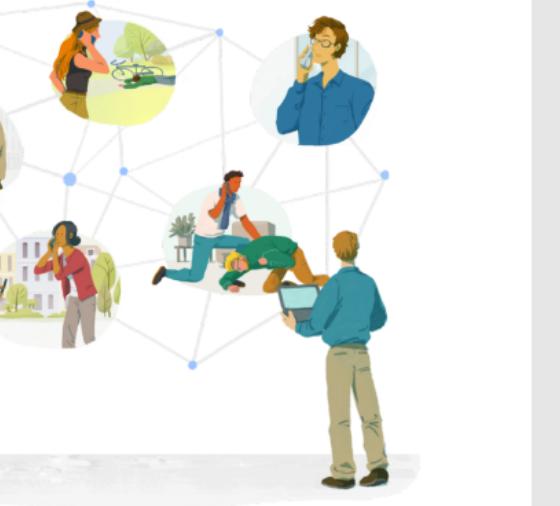

LLMs will likely play a central role in the future of medical documentation and communication. How do we get a grip of their uncertainty?

DISCUSSION

The role of uncertainty in an operational decision support system

- Are true uncertainty estimates really feasible?
Pragmatism versus idealism.
- Role of explainability compared to uncertainty estimates.
- European Parliamentary Research Services [18]:

"Future AI solutions for healthcare should be implemented by integrating uncertainty estimation, a relatively new field of research that aims to provide clinicians with clinically useful indications on the degree of confidence in AI predictions"

2024-03-04

UNCERTAINTY AND THE MEDICAL INTERVIEW

↳ discussion

↳ The role of uncertainty in an operational decision support system

1. LVMs were difficult to scale to the problems we care about.
2. LVMs did not convincingly outperform more pragmatic approaches (e.g. deferring).
3. Bayesian methods, deferring to predict, discriminative uncertainty.
4. What will happen if uncertainty estimates become a regulatory requirement?

DISCUSSION
The role of uncertainty in an operational decision support system

- Are true uncertainty estimates really feasible?
Pragmatism versus idealism.
- Role of explainability compared to uncertainty estimates.
- European Parliamentary Research Services [18]:
"Future AI solutions for healthcare should be implemented by integrating uncertainty estimation, a relatively new field of research that aims to provide clinicians with clinically useful indications on the degree of confidence in AI predictions"

Thank you for your attention.

- **Task:** Context, domain, language, culture, purpose.

└ introduction

└ Reliability of machine learning systems

1. So what are the challenges holding us back in implementing such systems?
 2. – Strong requirements of data.
 - Tasks that span different contexts, domains, languages, and cultures.
 - Regulatory requirements for transparency and accountability.
 - Trust and understanding of predictions.

Reliability of machine learning systems

- **Data:** Quality, quantity, diversity, bias, privacy, ethics.
- **Task:** Context, domain, language, culture, purpose.
- **Interpretability** of how a model works (transparency, accountability, regulation).
- **Explainability** of model predictions (trust, understanding, feedback).
- **Fairness** in treatment of different groups of people.
- **Robustness** to noise, outliers, distribution shift, and adversarial attacks.

HIERARCHICAL VAES KNOW WHAT THEY DON'T KNOW
An alternative likelihood bound, $\mathcal{L}^{>k}$

An alternative version of the ELBO that only partially uses the approximate posterior can be written as [40]

$$\mathcal{L}^{>k}(x; \theta, \phi) = \mathbb{E}_{p_{\theta}(z_{\leq k}|z_{>k})q_{\phi}(z_{>k}|x)} \left[\log \frac{p_{\theta}(x|z)p_{\theta}(z_{>k})}{q_{\phi}(z_{>k}|x)} \right] \quad (8)$$

Here, we have replaced the approximate posterior $q_{\phi}(z|x)$ with a different proposal distribution that combines part of the approximate posterior with the conditional prior, namely

$$p_{\theta}(z_{\leq k}|z_{>k})q_{\phi}(z_{>k}|x)$$

This bound uses the conditional prior for the lowest latent variables in the hierarchy.

UNCERTAINTY AND THE MEDICAL INTERVIEW

- 2024-03-04
- └ hierarchical vaes know what they don't know
 - └ An alternative likelihood bound, $\mathcal{L}^{>k}$

An alternative version of the ELBO that only partially uses the approximate posterior can be written as [40]

$$\mathcal{L}^{>k}(x; \theta, \phi) = \mathbb{E}_{p_{\theta}(z_{\leq k}|z_{>k})q_{\phi}(z_{>k}|x)} \left[\log \frac{p_{\theta}(x|z)p_{\theta}(z_{>k})}{q_{\phi}(z_{>k}|x)} \right] \quad (8)$$

Here, we have replaced the approximate posterior $q_{\phi}(z|x)$ with a different proposal distribution that combines part of the approximate posterior with the conditional prior, namely

$$p_{\theta}(z_{\leq k}|z_{>k})q_{\phi}(z_{>k}|x)$$

This bound uses the conditional prior for the lowest latent variables in the hierarchy.

1. So can we come up with a new bound that does not use the lowest latent variables in the same way?
2. So we could use this for OOD detection (as done in BIVA).

Likelihood ratios

We can use our new bound to compute the score used in a standard likelihood ratio test [9].

$$\text{LLR}^{>k}(x) \equiv \mathcal{L}(x) - \mathcal{L}^{>k}(x). \quad (9)$$

We can inspect what this likelihood-ratio measures by considering the exact form of our bounds.

$$\mathcal{L} = \log p_\theta(x) - D_{\text{KL}}(q_\phi(z|x) \| p_\theta(z|x)), \quad (10)$$

$$\mathcal{L}^{>k} = \log p_\theta(x) - D_{\text{KL}}(p_\theta(z_{\leq k}|z_{>k})q_\phi(z_{>k}|x) \| p_\theta(z|x)).$$

In the likelihood ratio the reconstruction terms cancel out and only the KL-divergences from the approximate to the true posterior remain.

$$\begin{aligned} \text{LLR}^{>k}(x) &= -D_{\text{KL}}(q_\phi(z|x) \| p_\theta(z|x)) \\ &\quad + D_{\text{KL}}(p_\theta(z_{\leq k}|z_{>k})q_\phi(z_{>k}|x) \| p_\theta(z|x)). \end{aligned} \quad (11)$$

Simulated prospective study

I. When is the model prediction presented to the call-taker?

1. Notify the call-taker after the call ends.
2. Notify the call-taker during the call.

II. How does prediction influence the diagnostic code the call-taker assigns to the call?

- A. Call-takers mirror model positives.
- B. Call-takers mirror model negatives.
- C. Call-takers mirror model predictions (corresponds to main results of the model itself).

To simulate the online scenario (2.), we stream the transcript to the model and make predictions every 50 words. A stroke positive is triggered only when three consecutive positive predictions are made. This is similar to the strategy implemented for a previous RCT on cardiac arrest [6].

The Ladder Variational Autoencoder (LVAE)

This is a Ladder VAE with three latent variables.

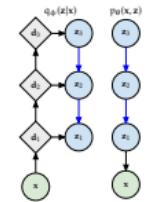

UNCERTAINTY AND THE MEDICAL INTERVIEW

└ vae background and the ladder variational autoencoder (lvae)

└ The Ladder Variational Autoencoder (LVAE)

This is a Ladder VAE with three latent variables.

Understanding the Ladder VAE is not so much about understanding the specific architecture as it is about:

- a) understanding the reason for choosing it,
- b) which other options were available,
- c) and why they don't work as well.

VAE BACKGROUND AND THE LADDER VARIATIONAL AUTOENCODER (LVAE)
A generative model from latent variables

Suppose data $\mathbf{x} \sim p(\mathbf{x})$ is generated via some underlying *latent* variable \mathbf{z} . Then

$$p(\mathbf{x}) = \int p(\mathbf{x}, \mathbf{z}) d\mathbf{z} = \int p(\mathbf{x}|\mathbf{z})p(\mathbf{z})d\mathbf{z}. \quad (12)$$

We would like to

- a) *infer* the latent variables \mathbf{z} given \mathbf{x}
- b) *generate* the observed variable \mathbf{x} given \mathbf{z}

UNCERTAINTY AND THE MEDICAL INTERVIEW
└ vae background and the ladder variational autoencoder (lvae)

VAE BACKGROUND AND THE LADDER VARIATIONAL AUTOENCODER (LVAE)
A generative model from latent variables

Suppose data $\mathbf{x} \sim p(\mathbf{x})$ is generated via some underlying latent variable \mathbf{z} . Then

$$p(\mathbf{x}) = \int p(\mathbf{x}, \mathbf{z}) d\mathbf{z} = \int p(\mathbf{x}|\mathbf{z})p(\mathbf{z})d\mathbf{z}. \quad (12)$$

We would like to

- a) infer the latent variables \mathbf{z} given \mathbf{x}
- b) generate the observed variable \mathbf{x} given \mathbf{z}

A small diagram showing a blue circle labeled 'z' connected by a line to a green circle labeled 'x', with the expression 'p(x, z)' above the 'z' node.

Exact inference

We can choose some simple model for $p(x, z)$ (denoted p_θ and parameterized by θ).

Bayes theorem then gives us the true model posterior,

$$p_\theta(z|x) = \frac{p_\theta(x,z)}{p_\theta(x)} = \frac{p_\theta(x|z)p_\theta(z)}{\int p_\theta(x|z)p_\theta(z)dz}. \quad (13)$$

But this only works if we can integrate over the latent variable z and the model $p_\theta(x|z)$.

2024-03-04

UNCERTAINTY AND THE MEDICAL INTERVIEW

- └ vae background and the ladder variational autoencoder (lvae)

- └ Exact inference

We can choose some simple model for $p(x, z)$ (denoted p_θ and parameterized by θ).

Bayes theorem then gives us the true model posterior,

$$p_\theta(z|x) = \frac{p_\theta(x,z)}{p_\theta(x)} = \frac{p_\theta(x|z)p_\theta(z)}{\int p_\theta(x|z)p_\theta(z)dz} \quad (13)$$

But this only works if we can integrate over the latent variable z and the model $p_\theta(x|z)$.

Exact inference becomes intractable

Suppose we want to model complex data where $|x| = D \gg 1$, such as images, audio or graphs.

We might choose to parameterize $p(x, z)$ with a neural network model with parameters θ and try to *learn* $p_\theta(x) \approx p(x)$.

$$p_\theta(x, z) = p_\theta(x|z)p(z) \quad (14)$$

where we could choose $p(z) = \mathcal{N}(0, 1)$.

However, this comes at the cost of making integrals over the latent variables intractable and hence, **we can no longer directly compute $p_\theta(x)$** .

vae background and the ladder variational autoencoder (lvae)

Exact inference becomes intractable

2024-03-04

Suppose we want to model complex data where $|x| = D \gg 1$, such as images, audio or graphs.
We might choose to parameterize $p(x, z)$ with a neural network model with parameters θ and try to *learn* $p_\theta(x) \approx p(x)$

$p_\theta(x, z) = p_\theta(x|z)p(z)$
where we could choose $p(z) = \mathcal{N}(0, 1)$.

However, this comes at the cost of making integrals over the latent variables intractable and hence, **we can no longer directly compute $p_\theta(x)$** .

Variational inference and the ELBOIntroduce some *variational* distribution $q_\phi(z|x)$ (parameterized by ϕ)

$$\begin{aligned}
 \log p(x) &= \log \int p_\theta(x, z) dz \\
 &= \log \int q_\phi(z|x) \frac{p_\theta(x, z)}{q_\phi(z|x)} dz \\
 &\geq \int q_\phi(z|x) \log \frac{p_\theta(x, z)}{q_\phi(z|x)} dz \\
 &= \mathbb{E}_{q_\phi(z|x)} \left[\log \frac{p_\theta(x, z)}{q_\phi(z|x)} \right] \\
 &= \mathbb{E}_{q_\phi(z|x)} \left[\log p_\theta(x|z) + \log p_\theta(z) - \log q_\phi(z|x) \right] \\
 &\equiv \underbrace{\mathcal{L}(x; \theta, \phi)}_{\text{evidence lower bound}}
 \end{aligned} \tag{15}$$

**UNCERTAINTY AND THE MEDICAL INTERVIEW**

└ vae background and the ladder variational autoencoder (lvae)

└ Variational inference and the ELBO

2024-03-04

VAE BACKGROUND AND THE LADDER VARIATIONAL AUTOENCODER (LVAE)
Variational inference and the ELBO
Introduce some *variational* distribution $q_\phi(z|x)$ (parameterized by ϕ)

$$\begin{aligned}
 \log p(x) &= \log \int p_\theta(x, z) dz \\
 &= \log \int q_\phi(z|x) \frac{p_\theta(x, z)}{q_\phi(z|x)} dz \\
 &> \int q_\phi(z|x) \log \frac{p_\theta(x, z)}{q_\phi(z|x)} dz \\
 &= \mathbb{E}_{q_\phi(z|x)} \left[\log \frac{p_\theta(x, z)}{q_\phi(z|x)} \right] \\
 &= \mathbb{E}_{q_\phi(z|x)} \left[\log p_\theta(x|z) + \log p_\theta(z) - \log q_\phi(z|x) \right] \\
 &\equiv \underbrace{\mathcal{L}(x; \theta, \phi)}_{\text{evidence lower bound}}
 \end{aligned} \tag{15}$$

The variational autoencoder (VAE)

© corti

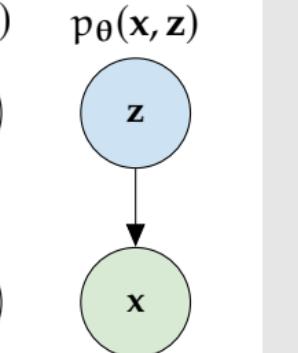

Suppose we parameterize $q_\phi(z|x)$ by a model with parameters ϕ . Then we can optimize both $\{\theta, \phi\}$ jointly by maximizing the ELBO.

$$\{\theta^*, \phi^*\} = \arg \max_{\{\theta, \phi\}} \mathcal{L}(x; \theta, \phi) \quad (16)$$

The result is the VAE [33] consisting of

- a) an *inference model* (or *encoder*) $q_\phi(z|x)$ which approximates the intractable true posterior $p(z|x)$.
- b) a *generative model* (or *decoder*) $p_\theta(x|z)$ which can generate new samples from the prior $p(z)$, or "reconstruct" with proposals from $q_\phi(z|x)$.

Limitations of VAEs

The VAE uses a mean field approximation for most common variational posteriors.

$$q(\mathbf{z}) = \prod_i q(z_i) \quad (17)$$

- Assumes independence between latent variables.
- Model cannot learn covariance between latents.
- This limits expressivity as we cannot expect to always match the true posterior well.

E.g. a vehicle's color is often dependent on its type (fire truck, police car, bus, taxi etc.) but these are coded independently in \mathbf{z} .

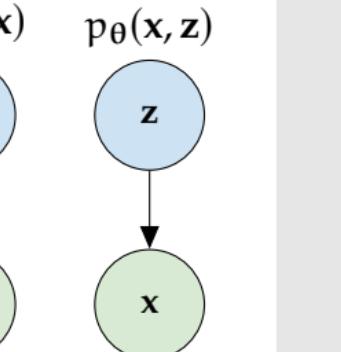

2024-03-04

VAE BACKGROUND AND THE LADDER VARIATIONAL AUTOENCODER (LVAE)

Hierarchical VAE

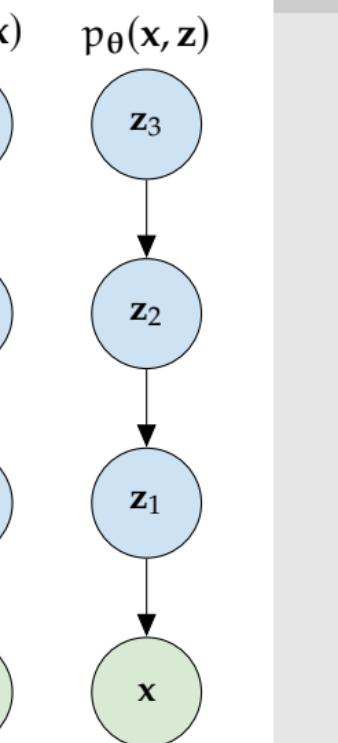

To avoid these limitations, we can introduce a hierarchy of additional latent variables $\mathbf{z} = \mathbf{z}_1, \dots, \mathbf{z}_L$. For $L = 3$,

$$p_{\theta}(\mathbf{x}|\mathbf{z}) = p_{\theta}(\mathbf{x}|\mathbf{z}_1)p_{\theta}(\mathbf{z}_1|\mathbf{z}_2)p(\mathbf{z}_3). \quad (18)$$

We can straightforwardly generalize the inference model,

$$q_{\phi}(\mathbf{z}|\mathbf{x}) = q_{\phi}(\mathbf{z}_1|\mathbf{x})q_{\phi}(\mathbf{z}_2|\mathbf{z}_1)q_{\phi}(\mathbf{z}_3|\mathbf{z}_2). \quad (19)$$

This is called *bottom-up* inference.

We can straightforwardly generalize the inference model,

$$q_{\phi}(\mathbf{z}|\mathbf{x}) = q_{\phi}(\mathbf{z}_1|\mathbf{x})q_{\phi}(\mathbf{z}_2|\mathbf{z}_1)q_{\phi}(\mathbf{z}_3|\mathbf{z}_2).$$

This is called *bottom-up* inference.

Challenges of hierarchical VAEs

Consider a simple model $p_{\text{simple}}(x)$ without any latent variables. We can rewrite the likelihood as,

$$\begin{aligned} \mathbb{E}_{p(x)} [\log p_{\text{simple}}(x)] &= \mathbb{E}_{p(x)} \left[\log \left(p(x) \frac{p_{\text{simple}}(x)}{p(x)} \right) \right] \\ &= - \underbrace{\mathcal{H}(p)}_{\text{data entropy}} - \underbrace{D_{\text{KL}}(p(x) || p_{\text{simple}}(x))}_{\text{divergence from data distribution}} \end{aligned}$$

where $\mathcal{H}(p) = \mathbb{E}_{p(x)}[\log p(x)]$.

UNCERTAINTY AND THE MEDICAL INTERVIEW

- └ vae background and the ladder variational autoencoder (lvae)
- └ Challenges of hierarchical VAEs

2024-03-04

Consider a simple model $p_{\text{simple}}(x)$ without any latent variables. We can rewrite the likelihood as,

$$\begin{aligned} \mathbb{E}_{p(x)} [\log p_{\text{simple}}(x)] &= \mathbb{E}_{p(x)} \left[\log \left(p(x) \frac{p_{\text{simple}}(x)}{p(x)} \right) \right] \\ &= - \underbrace{\mathcal{H}(p)}_{\text{data entropy}} - \underbrace{D_{\text{KL}}(p(x) || p_{\text{simple}}(x))}_{\text{divergence from data distribution}} \end{aligned}$$

where $\mathcal{H}(p) = \mathbb{E}_{p(x)}[\log p(x)]$.

Challenges of hierarchical VAEs

Let's do the same for a VAE $p_\theta(x)$ with ELBO given by

$$\log p_\theta(x) \geq \mathbb{E}_{q_\phi(z|x)} \left[\log \frac{p_\theta(x|z)p_\theta(z)}{q_\phi(z|x)} \right]. \quad (20)$$

The expectation over the data becomes,

$$\begin{aligned} \mathbb{E}_{p(x)} [\log p_\theta(x)] &\geq \mathbb{E}_{p(x)} \left[\log \left(p(x) \frac{p_\theta(x)}{p(x)} \right) \right] \\ &= -\mathcal{H}(p) - D_{KL}(p(x)||p_\theta(x)) \\ &\quad - \underbrace{\mathbb{E}_{p(x)} [D_{KL}(q_\phi(z|x)||p_\theta(z|x))]}_{\text{divergence from true posterior}} \end{aligned} \quad (21)$$

Compared to the simple model, we incur an **additional cost** for the latent variable given by the divergence from the true model posterior.

2024-03-04

UNCERTAINTY AND THE MEDICAL INTERVIEW

vae background and the ladder variational autoencoder (lvae)

Challenges of hierarchical VAEs

VAE BACKGROUND AND THE LADDER VARIATIONAL AUTOENCODER (LVAE)
Challenges of hierarchical VAEs
Let's do the same for a VAE $p_\theta(x)$ with ELBO given by

$$\log p_\theta(x) > \mathbb{E}_{q_\phi(z|x)} \left[\log \frac{p_\theta(x|z)p_\theta(z)}{q_\phi(z|x)} \right]. \quad (20)$$

The expectation over the data becomes,

$$\begin{aligned} \mathbb{E}_{p(x)} [\log p_\theta(x)] &> \mathbb{E}_{p(x)} \left[\log \left(p(x) \frac{p_\theta(x)}{p(x)} \right) \right] \\ &= -\mathcal{H}(p) - D_{KL}(p(x)||p_\theta(x)) \\ &\quad - \mathbb{E}_{p(x)} [D_{KL}(q_\phi(z|x)||p_\theta(z|x))] \end{aligned} \quad (21)$$

Compared to the simple model, we incur an **additional cost** for the latent variable given by the divergence from the true model posterior.

Challenges of hierarchical VAEs

For a hierarchical VAE with two latent variables

$$\begin{aligned}
 \mathbb{E}_{p(x)} [\log p_{\theta}(x)] &\geq \mathbb{E}_{p(x)} \left[\log \left(p(x) \frac{p_{\theta}(x)}{p(x)} \right) \right] \\
 &= -\mathcal{H}(p) - D_{KL}(p(x)||p_{\theta}(x)) \\
 &\quad - \mathbb{E}_{p(x)} \mathbb{E}_{q_{\phi}(z_1|x)} [D_{KL}(q_{\phi}(z_2|z_1)||p_{\theta}(z_2|z_1))] \\
 &\quad - \mathbb{E}_{p(x)} [D_{KL}(q_{\phi}(z_1|x)||p_{\theta}(z_1|x))] \tag{22}
 \end{aligned}$$

The cost is **incurred for each additional latent** we add to the hierarchy.

Hence, each latent will only be used by the model if we get an **opposite equal or larger improvement** in the ELBO.

vae background and the ladder variational autoencoder (lvae)

Challenges of hierarchical VAEs

2024-03-04

VAE BACKGROUND AND THE LADDER VARIATIONAL AUTOENCODER (LVAE)
Challenges of hierarchical VAEs

$$\begin{aligned}
 \mathbb{E}_{p(x)} [\log p_{\theta}(x)] &\geq \mathbb{E}_{p(x)} \left[\log \left(p(x) \frac{p_{\theta}(x)}{p(x)} \right) \right] \\
 &= -\mathcal{H}(p) - D_{KL}(p(x)||p_{\theta}(x)) \\
 &\quad - \mathbb{E}_{p(x)} \mathbb{E}_{q_{\phi}(z_1|x)} [D_{KL}(q_{\phi}(z_2|z_1)||p_{\theta}(z_2|z_1))] \\
 &\quad - \mathbb{E}_{p(x)} [D_{KL}(q_{\phi}(z_1|x)||p_{\theta}(z_1|x))] \tag{22}
 \end{aligned}$$

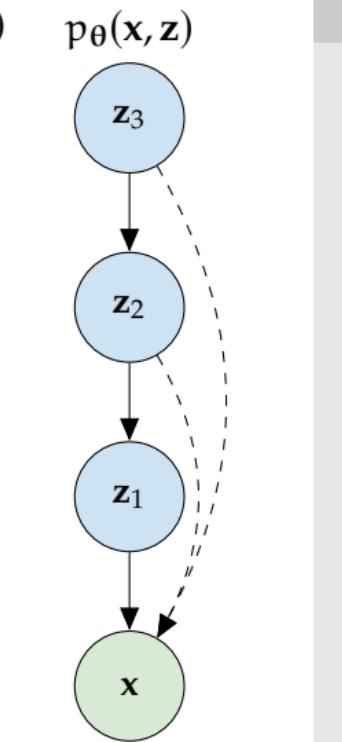

The cost is incurred for each additional latent we add to the hierarchy.
Hence, each latent will only be used by the model if we get an opposite equal or larger improvement in the ELBO.

(Failing to) Dodge the challenges

There's a few common ways to try and dodge these issues:

- Skip connections [16, 40]
- Free bits in the KL-terms [34]
- Deterministic warmup [53]
- Batch normalization/weight normalization [28, 49]

None of them work for more than around 5 latent variables.

UNCERTAINTY AND THE MEDICAL INTERVIEW
